

CLINICAL PSYCHOLOGY AND LEVELS OF REALITY
PART I - ESP AS A COMPONENT IN SOME PSYCHIC
GICAL DISORDERS

Abstract: Clinical Psychology has not taken into account evidence provided by other areas of research that point to the existence of other levels of reality. Therefore, that which is not perceived through physical senses is often considered as being of a pathological nature. The authors have observed that in some psychological disorders sometimes there is an ESP factor mingled with the symptoms, and which are only taken into account as a proof of "insanity". Reports made by some patients' and trained sensitized about their perceptions are similar. The difference between lies in the fact that the former experience their perceptions in a chaotic manner and are overwhelmed by them, while the latter learned to discriminate between ESP and common perceptions, maintaining their psychical integrity.

When in 1882 the Society for Psychical Research of London started making scientific studies of paranormal phenomena, the model of reality conceived was dictated by Newtonian Physics - and in this model there was no place for phenomena which conflicted with the principles.

But the theory of Relativity as well as the developments of Modern Physics shattered this model of a mechanistic and orderly Universe. Today we know that Classic Physics became limited because it only described a certain level of reality - the level that we perceive through our senses. However, it was not adequate to describe phenomena that take place at the sub-atomic level and which affect our perception.

For a long time Parapsychology has been studying phenomena which point to other levels of reality. What makes these observations important is that they originate from different areas of research, which, on comparison, form a network of evidence pointing to other levels of reality.

The nature of reality is questioned both by physicists and psychologists. Einstein commented on this question as follows: "The material world... constitutes the whole world of appearance, not the whole world of reality; we may think of it as forming a cross section of the world of reality."

Psychology has always strived for respectability as a science. For this reason it adopted the parameters of Classic Physics in order to attain the same precision and objectivity. However, it did not keep pace with the evolution of Physics and Parapsychology and without questioning more deeply its basic assumptions, it remained within the theoretical model proposed by Classic Physics.

It tells us that questioning reality has much to do with Clinical Psychology because, as psychotherapists, we deal with human beings and their subjective reality - and this often means that we have to deal with the so called altered states of consciousness. The main aspect of this question is that the expression of the ASC may be adapted to clinical practice and also in our parapsychological research.

We have noticed that in many cases which could be considered as borderline pathology, there is an ESP factor mingled with the symptoms and the behaviour of the patient. As examples we cite cases of some of our patients that could be included in this category.

Case BE - We had a patient who complained, amongst other things, that she sometimes felt as if she were floating near the ceiling. Once, at that position, she saw her body sitting on the easy chair in front of a group of people who had come to visit her. Another patient reported that several times she felt as if she moved out of her body reaching the wall opposite to her bed and that, from there, she could see her own body lying on the bed. It is more than natural experiences of this nature trigger a psychological reaction leading the patient to doubt her sanity.

Psychokinetic phenomena - We have a patient who hears noises and observes movements in the house: crashes in the kitchen, doors that close, objects changing place, etc. From the traditional point of view we would say that she is hallucinating. However, due to our knowledge and experience with the phenomenon of poltergeist, we came to the conclusion that she was not hallucinating. Recently, members of the family have heard and seen the same things, confirming that our reasoning was correct. Psychokinetic phenomena are not uncommon. Not knowing about them, however, may cause the development of psychological problems associated to the stress.

Precognition - We had a patient who had precognitive dreams, connected with the death or accidents with relations or acquaintances. These precognitive dreams led to the development of a rational thought loaded with guilt. This sense of guilt was dealt with in psychotherapy making her aware that there was no direct relationship between this type of dream and the death or accidents of the people she knew. She was also made aware of her ESP capacity. In addition, psychotherapy dreams are often regarded as a catharsis of unconscious desires. However, sometimes they may also be a bridge between other levels of reality and ours. Psychotherapists who work with the interpretation of dreams should be well aware of this fact.

Following up symptoms - We had opportunity of following up cases of people displaying somatic or psychological symptoms, making them seek doctors or psychologists. The treatments, however, were not successful. We came across the same type of phenomenon in our clinical

practice. We also noticed that these symptoms shifted, leading to a different diagnosis by different specialists. Our observations indicate that certain people have a sensitivity which causes them to unknowingly act as "lightning conductors" in their environment, picking up moods or physical symptoms of the people nearby. When trained to develop their ESP faculty, they learn to control it and are no longer at its mercy. Trained sensitives can often manifest the symptoms experienced by a patient they do not know at the time of his name, whether the patient is known or unknown to those present. There are persons who possess this faculty but are unaware of it and suffer the influences of their environment.

For the last few years we have studied people with ESP and these studies indicate that in certain disturbances classified as "illness" there are ESP components. Usually an ESP manifestation looked upon as another element pointing to the fact that the individual is insane. ESP truly has its part in this picture, because it makes the individual receptive to influences of many kinds; and also reinforces the idea the patient himself and others have of a disturbance, i.e., he is most probably becoming insane, due to weird perceptions and sensations he experiences.

It is impossible to ignore the similarities between certain perceptions of patients committed to asylums and the description given to sensitives. The difference, in terms of what is experienced, lies in the fact that trained sensitives discriminate between ESP and common perception, while the person who is a sensitive but not aware of it, gets in emotional states which end by creating or aggravating maladjustment.

Clairvoyance is often found in people who are diagnosed as "mentally ill". What they perceive is not taken into account as it is considered the result of a sick mind. Their perceptions are only taken into account as one more proof of their "insanity". However, clairvoyance as well as clairaudience are often found in sensitives.

Here again there is a difference not in that which is perceived rather in the experience triggered by the perception. The psychically experiences his perception in a chaotic manner and is overwhelmed by it; the trained sensitive learns to control his ESP; he may have the same perceptions, but maintains his psychical integrity.

There are also innumerable patient reports regarding the perception or sensing of what they describe as entities at their side. To a briefing on such cases it is sufficient to consult a few psychopathology textbooks or to visit some psychiatric institutions and chat with patients. It is interesting to note that no matter the environment or the cultural background from which the patient comes, that which is perceived has similar characteristics in a great number of cases, pointing to a universality in the content of what is perceived. We believe that this content is universal because it deals with another level of reality which can also be perceived by persons who are adapted and possess ESP.

As a working hypothesis, we consider that these entities (seen, felt or perceived as "voices") exist in another level of reality. In our paper, presented at the III International Conference on

Electronic Research, in 1977, in Tokyo, entitled "Healing at a distance: Some Evidences Suggestive of Theta Agent Influence in Psychological Disturbances", we named these entities "theta agents".

One may consider these "theta agents" as natural phenomena, there may be subject to the laws of Nature, or we can also give them a religious connotation. From our point of view, however, the religious aspect that these phenomena might have is due to Man's interpretation and not to the phenomena itself. As our working hypothesis, we are for the existence of theta agents. We did this because apart from the explanation one might give them - subconscious of the sensitive, fraud, telepathy, clairvoyance, "this world-ESP", etc. - we have noticed the influence of such theta agents on some patients. In most of the cases they can be removed through certain processes we use. The theta agents were merely the result of the subjectivity of the sensitive or due to his ESP, the improvement we noticed due to their means we applied would not have occurred.

The way theta agents act and how they present themselves was described in the paper mentioned previously, as well as in the second part of this paper which is being presented at this IV Conference, under the title "ESP as an Aid to Psychotherapy in Some Psychological Disorders".

It is natural that ESP should not be uniform in everyone. The intensity of the manifestations vary from person to person and so does the type of ESP. In the same manner, the way ESP manifests itself interferes in the patient's life is closely related to the structure of his personality. These two aspects are closely interrelated and consequently the effects of this interrelation vary from person to person.

On the other side to this question is the influence theta agents have on certain persons, whether they have or do not have ESP. The effect of the influence may be psychopathological, psychophysiological or environmental. The difference felt between people who have or do not have ESP is that the former can become mentally confused as they feel or hear things that other people do not.

The patient may feel at the mercy of "supernatural" forces with no possibility of controlling them. The fear of being different from others and, as such, running the risk of being called "insane" and perhaps being committed to an asylum, acts as another destructive factor.

We know sensitives who have gone through this experience but who have overcome the maladjustment caused by their untrained ESP; they have learned to deal with it using it to their own benefit and also to help others.

As psychotherapists we should be alert to patients' reports, trying to apprehend their reality however strange it may seem to us, and without being overconcerned with fitting their symptoms into one of the pre-established psychopathological categories. As we get to know our patients, we become familiar with the dynamics and structure of their personality, enabling us to understand and perceive their problems better. If we detect a particular type of entity, it should be our duty to make them aware of it, helping them

understand what is happening. When ESP experiences are no longer felt as a threat, the activation of internal resources during therapy allow the patient to mitigate or overcome resistances, actualizing his tendency towards recovery.

The purpose of this paper is to expand the traditional concept of the individual vs. environment, taking into account the possibility of other levels of reality which can interact with the individual. It is not our intention to substitute today's psychotherapeutic knowledge - but only to add to it another dimension, aiming at a holistic understanding of the patient and his reality, as well as his recovery.

Abstract: The authors discuss the interactions between other levels of reality and ours in cases involving patients with psychological disorders of various kinds. Trained sensitives were used in this study and often manifested extraneous personalities (named theta agents by the authors), and who were involved with the patients. A description is made of the theta agents observed and their interaction with the patients. Removal of theta agents by means of hypnosis procedures is followed by an improvement in the patients' condition. This approach combined with traditional psychotherapy opens up new possibilities for patients whose prognosis of recovery is remote or dependent on extensive psychotherapy.

Introduction

In 1977, at the III International Conference on Psychotronic Research in Tokyo, we presented a paper discussing the possibility of influencing at a distance people with various types of psychological disorders, aiming at relieving or removing the symptoms of these disorders. After experimenting during three years, we had come to the conclusion that this could be done. However, we also found out that some personalities extraneous to the members of the group in some cases manifested themselves, suggesting an interrelation between psychological disorders of some patients and the influence of these personalities - which we named "theta agents". Also in this paper, we described the types of theta agents we came across, as well as the improvements and relapses observed in patients as well as with these agents. The subjects selected for our sample did not know that they were being focused by the group, were not undergoing psychotherapy and had been showing certain symptoms for more than a year.

The purpose of this paper is to take up these aspects and extend them based on observations made during the last two years.

Working Hypothesis

Our observations, as pointed out in our paper "ESP as a Component of Some Psychological Disorders", which is being presented at this conference, led us to consider that there might be another level of reality, unperceived by our senses, but which could interact with the individual. Apparently, besides the classical interaction of the individual vs. environment, there could be a third one that we would call "spiritual". "Spiritual" is probably not the best word
