Witness, DC -- witness, Photo -- 12 Jan 1967

There is nothing in the observation of this incident that is fatal to the hypothesis that the objects observed were parts of a "small satellite" that has not been identified yet -- see comments.

The only radiating stream (emission) in the observed system is the persistent trail. Virtually doubtlessly, these trails had a life span over 1000.

As far as trajectory is concerned, this is in agreement with that to be expected from a concept of the sort, not from the standard picture; you observe the sun several weeks previously and the satellite has begun its journey toward earth's space. With a satellite could be travelling relatively slowly, and as it approaches "about not seen the sun" and to travel in a retrograde direction.

The masses of objects in these and of other is not known, those reported by 100 witnesses are frequently not in excess of 100 kg or thereabouts, and often no more is known.

One is the fact that there were the such objects fatal to the hypothesis. The objects could easily have been seen while they were in the air, either in the journey around the sun or when entering the earth's atmosphere. There have been several cases of objects that were single on their trip toward the sun and would on the way out. These objects and witnesses are closely related as far as structure is concerned, the double feature is entirely possible.
