

A LIGHT IN THE NIGHT.

From "Scout":—"On Saturday night, about 8.30, I and another person saw a strange light in the sky in the west. It was much too big for a meteor, and was travelling too slowly, and had no bright centre. It was a cloudy night, and the light appeared at the back of the clouds. It might be best described as resembling a tadpole in shape, and it travelled horizontally from west to south-west. About eight minutes later it reappeared and moved from south-west to west. Could your readers offer any explanation? It might have been a ray of light thrown on the clouds by a powerful searchlight, but there was no 'beam' visible."
