If EL are plasmas of some kind, then they can glow brightly in the dark \*and\* quite readily appear shiny and metallic in daylight (or even artificial light). They are also likely to appear spherical, and, quite possibly, discoid.

Speaking for my own part, on something that is loosely related, in 1967, in brilliant sunny weather in Suffolk, England, I and one other witness saw a perfectly, utterly, pitch-black flying object at a little above tree-top height at about a half-mile distance. It was round, but whether it was a globe, a disc on edge or some kind of supernatural 'black hole' it was impossible to tell, because there was no reflection from this thing. It then vanished before our eyes, only to reappear moments later about a quarter of a mile further on, whereupon it flew up out of sight (we were passengers travelling in a car).

There are reports of black ball lightning too. My own guess is that these black objects are the 'opposite pole' to lights, representing a literal black hole sucking in photons. Shining plasma-type EL and these black holes could represent a sort of anode-diode polarity to the phenomenon, perhaps.

Whatever, EL do not appear only as LITS.

Regards,  
Paul
